TITANIC PROJECT RESULTS

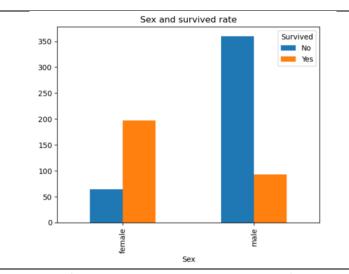

1. Determine if the survival rate is associated with the class of passengers.

- The first thing that we can comment it's that the bars don't look alike, so these two variables may be dependent.
- The second thing is that in the first class, more people survived, in the second class the numbers are very similar, but more people did not survive and in the third class, we can see how high the number of people that did not survive was.
- 2. Determine if the survival rate is associated with gender.

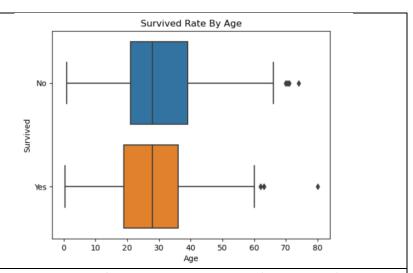

- The first thing that we can comment it's that in this case, also, the bars don't look alike, so it is possible that these two variables are dependent.
- The second thing is we can see the difference in survival rates between the two genders. There are more women who survived by far than men.

3. Determine the survival rate is associated with age.

Survived	Yes	No
Age		
Count	290	492
Mean	28	31
Std	15	14
Min	0	1
Max	80	74
25%	19	21
50%	28	28
75%	36	39

In this comparison, we can notice how the median of both groups is the same (28 years old) but there is a tiny difference between the means, the mean of the people who survived is 28, lower than the mean of the people who did not survive which is 31. Also, we can add that in the non-survival people the group is a little bit more concentrated in older ages.
